1 Introduction

Classification in statistical analysis is a useful tool, e.g. for predicting outcomes of various situations or classifying and sorting large amounts of data.

Learning Repository [3]. We will use these methods to classify data of credit card clients' default payment from a Taiwanese bank. Additionally, we will use the MLP to solve a regression problem on Franke's function and compare the result from a prior project where we used standard least squares to solve the regression problem [1].

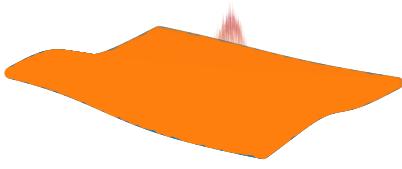

Figure 1: TEST FIGURE AS PLACEHOLDER,
PLEASE REMOVE FROM FINAL VERSION

The aim of this project is to study classification and regression problems through our own implementation of logistic regression and a multilayer perceptron (MLP) in Python. This particular data set has been used in a prior research paper by Yeh, I. C. and Che-hui Lien about data mining techniques [4], and can be downloaded from the UCI Machine

2 Theory

2.1 Stochastic Gradient Descent (SGD)

217.98259pt

2.2 Logistic Regression (LR)

2.3 Artificial Neural Networks (ANN)

In an artificial neural network, something something nodes. The output of the nodes in each layer is given by the value of a chosen activation function $f(z)$.

2.3.1 Multilayer perceptron

The multilayer perceptron is a feedforward neural network.

The activation of the j th neuron of layer l is defined as

$$z_j^l = \sum_{i=1}^{M_{l-1}} w_{ij}^l a_j^{l-1} + b_j^l, \quad (1)$$

where b_j^l and w_{ij}^l are the biases and weights at layer l , and $a_j^l = f(z_j^l)$.

To calculate the optimal biases and weights for the problem, we initialize the gradients of the cost function \mathcal{C} with respect to the weights W and biases b at the output layer $l = L$ and the output error δ_L as

$$\frac{\partial \mathcal{C}}{\partial w_{jk}^L} = \delta_j^L a_k^{L-1}, \quad (2)$$

$$\frac{\partial \mathcal{C}}{\partial b_j^L} = \delta_j^L, \quad (3)$$

$$\delta_j^L = f'(z_j^L) \frac{\partial \mathcal{C}}{\partial a_j^L}, \quad (4)$$

before propagating backwards through the hidden layers using the general equations

$$\frac{\partial \mathcal{C}}{\partial w_{jk}^l} = \delta_j^l a_k^{l-1}, \quad (5)$$

$$\frac{\partial \mathcal{C}}{\partial b_j^l} = \delta_j^l, \quad (6)$$

$$\delta_j^l = \sum_k \delta_k^{l+1} w_{kj}^{l+1} f'(z_j^l). \quad (7)$$

Looking at these equations, it is clear that the chosen cost function \mathcal{C} should be differentiable.

The biases can be initialized to zero, but we have chosen an initial value of 0.01 to ensure that all of the neurons have some initial output. Initializing the weights to zero, however, will result in all neurons outputting the same value. Instead, the weights are initialized with values from a uniform distribution with $w_{kj} \in (-1/\sqrt{n}, 1/\sqrt{n})$ to ensure uniform learning [2].

3 Data

3.1 Classification - Credit card client data

For the classification part of this project, we are using credit card payment data from a Taiwanese bank downloaded from the UCI Machine Learning Repository. The response variable is a binary variable of default payment with Yes = 1, No = 0. The original data set consists of 30 000 observations, with X amount of observations with default payments. There are 23 explanatory variables, cited from the original paper they are described as [4]:

- X1: Amount of the given credit (NT dollar): it includes both the individual consumer credit and his/her family (supplementary) credit.
- X2: Gender (1 = male; 2 = female).
- X3: Education (1 = graduate school; 2 = university; 3 = high school; 4 = others).
- X4: Marital status (1 = married; 2 = single; 3 = others).
- X5: Age (year).
- X6 - X11: History of past payment. We tracked the past monthly payment records (from April to September, 2005) as follows: X6 = the repayment status in September, 2005; X7 = the repayment status in August, 2005; . . . , X11 = the repayment status in April, 2005. The measurement scale for the repayment status is: -1 = pay duly; 1 = payment delay for one month; 2 = payment delay for two months; . . . ; 8 = payment delay for eight months; 9 = payment delay for nine months and above.
- X12-X17: Amount of bill statement (NT dollar). X12 = amount of bill statement in September, 2005; X13 = amount of bill statement in August, 2005; . . . ; X17 = amount of bill statement in April, 2005.
- X18-X23: Amount of previous payment (NT dollar). X18 = amount paid in

September, 2005; X19 = amount paid in August, 2005; . . . ; X23 = amount paid in April, 2005.

3.2 Regression - Franke's function

For the regression part part of this project we will be performing regression analysis on Franke's function $g(x, y)$ with added Gaussian noise $\varepsilon \sim N(0, \sigma^2)$. Franke's function is given by

$$\begin{aligned} g(x, y) = & \frac{3}{4} \exp \left(-\frac{(9x-2)^2}{4} - \frac{(9y-2)^2}{4} \right) \\ & + \frac{3}{4} \exp \left(-\frac{(9x+1)^2}{49} - \frac{(9y+1)^2}{10} \right) \\ & + \frac{1}{2} \exp \left(-\frac{(9x-7)^2}{4} - \frac{(9y-3)^2}{4} \right) \\ & - \frac{1}{5} \exp(-(9x-4)^2 - (9y-7)^2) \end{aligned} \quad (8)$$

and is defined on $x, y \in [0, 1]$. The data we are fitting is given by

$$G(x, y) = g(x, y) + \varepsilon.$$

4 Model evaluation

4.1 Regression

To evaluate the performance of our regression model, we consider the R^2 score, given by

$$R^2(\mathbf{y}, \hat{\mathbf{y}}) = 1 - \frac{\sum_{i=0}^{n-1} (y_i - \hat{y}_i)^2}{\sum_{i=0}^{n-1} (y_i - \bar{y})^2}, \quad (9)$$

where \mathbf{y} is the given data, $\hat{\mathbf{y}}$ is the model and \bar{y} is the mean value of \mathbf{y} .

4.2 Classification

To evaluate the performance of our classification model, we consider the accuracy score, given by

$$\text{accuracy} = \frac{\sum_{i=1}^n I(t_i = y_i)}{n}, \quad (10)$$

where t_i is the target, y_i is the model output, n is the number of samples and I is the indicator function,

$$I = \begin{cases} 1, & t_i = y_i \\ 0, & t_i \neq y_i \end{cases}.$$
